

# How to push your changes to Heroku?

## 1) Heroku cli

- It will create a new empty application on Heroku, along with an associated empty Git Repository. If you run this command from your app's root directory, the empty git repository is automatically set as a remote for your local repository

## 2) git remote -v (Optional)

- It is used to check the remote name

## 3) git remote rename heroku new-heroku (Optional)

- It is used to change the name of your remote

## 4) git push new-heroku master (Here new-heroku is my remote name)

- It is used to push the code from your local repository's master branch to your heroku remote's master branch
